How to make WWT more of a research tool?

The screenshot displays the WorldWide Telescope (WWT) web client interface. At the top, a navigation bar includes 'Home', 'Explore', 'Guided Tours', 'Search', 'Communities', 'View', and 'Settings'. On the right, there are buttons for 'Install Windows Client' and 'Sign Out'. Below the navigation bar, a 'Collections' section shows various data sources like 'New VAMP Feeds', 'Constellation', 'All-Sky Surveys', 'Spitzer Studies', 'Chandra Studies', 'Hubble Studies', 'Astrophotography', 'Radio Studies', 'NOAO Studies', 'Gemini Studies', and 'Messier Catalog'. A blue callout box points to the 'All-Sky Surveys' collection with the text 'multiple cooperating data repositories queried at once'. Another blue callout box points to the 'New VAMP Feeds' collection with the text 'sharing and saving options'. The main view shows a detailed image of the Andromeda Galaxy (M31) with a central crosshair and a circular zoomed-in view of the core. A blue callout box points to this zoomed-in view with the text 'High-Dimensional (interactive) Visualizaton'. A context menu is open over the zoomed-in view, listing options: 'Name: M31', 'Information', 'Imagery', 'Set as Background Imagery', 'Set as Foreground Imagery', 'Look up on Bing', 'Look up on SIMBAD', 'Look up on SEDS', 'Look up on Wikipedia', and 'Look up publication on ADS'. A blue callout box points to the 'Look up on NED' option with the text 'smart suggestions about related information'. At the bottom, there are controls for 'Look At' (set to 'Sky'), 'Imagery' (set to 'Digitized Sky Survey (Color)'), and a 'Tracking' section for the 'Andromeda Galaxy' with a '1 of 2' indicator. A small map of the constellation Andromeda is shown in the bottom right corner with coordinates RA: 00h42m44s and Dec: +41:16:09.

The screenshot shows the Power BI 'Get Data' interface. The left sidebar includes 'My Workspace', 'Content Pack Library', 'My Organization', 'Services', 'Samples', 'Import or Connect to Data', 'Files', and 'Databases & More'. The main area shows a breadcrumb path: 'Get Data > Databases & More > Azure SQL Database'. Below this, four data source options are displayed: 'Azure SQL Database', 'Azure SQL Data Warehouse', 'SQL Server Analysis Services', and 'Spark on Azure HDInsight'. The 'Azure SQL Database' option is selected and highlighted. Below the options, the 'Azure SQL Database' section is expanded, showing a description: 'Azure SQL Database is a fully managed relational database-as-a-service that makes tier-1 capabilities easily accessible. SQL Database supports massive scale-out, predictable performance, flexible manageability and includes built-in high availability and self-management for near-zero maintenance. With Power BI, you can create dynamic reports, mashups with data and metrics you already have in your Azure SQL Database.' A yellow 'Connect' button with an arrow icon is visible, along with a 'Learn More' link.

Remote Access & Dataverse, e.g. milkyway3d.org

Milky Way 3D Galactic Plane Coverage Tool

MilkyWay3D.org is a tool intended to organize and curate links to information about data sets relevant to our 3D understanding of the Milky Way. For any given longitude range, we provide the means to determine the available surveys, their overlapping footprint, and the type of data each provides. Information about each dataset, including how to access the data, their hallmark publications, and their principal investigators, is available at the [Milky Way 3D Dataverse](#). All the data can be loaded, "linked", and explored using the new 3D visualization software package Glue, available for download at [glueviz.org](#)

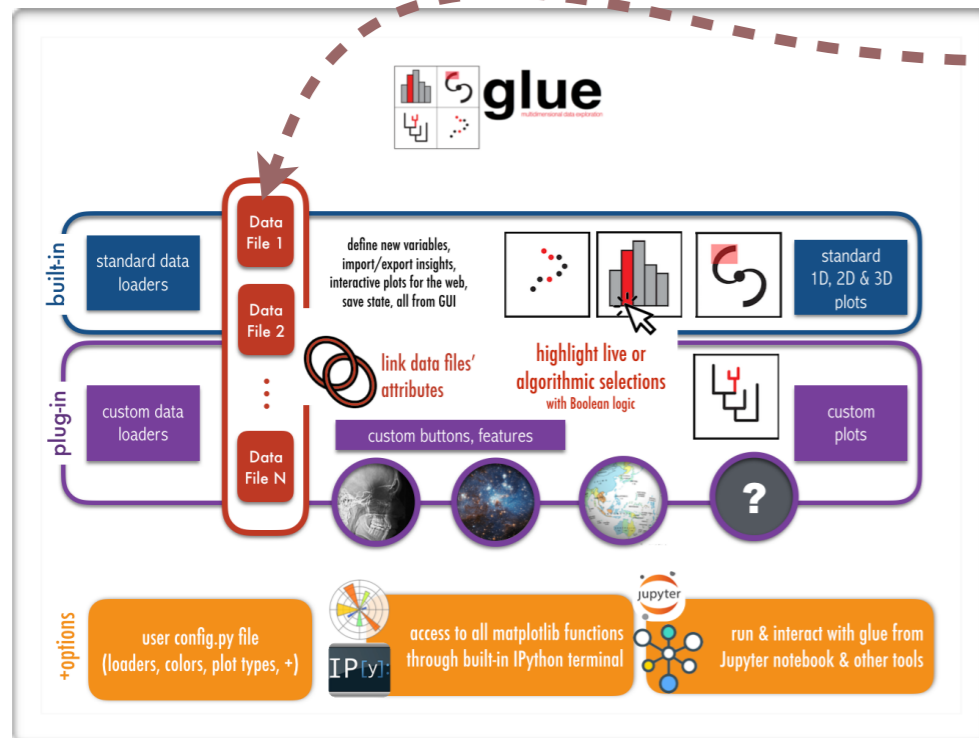

This is an interactive coverage tool of surveys of the galactic plane created with the [AAS WorldWide Telescope API](#), and [WorldWide Telescope](#). To view the coverage of a region, click on the check box or slider in the first column of the table below. You can drag your mouse to pan or zoom in the window. Information on where to find the data in the regions may be found by clicking on the region name or the ★. Table columns may be sorted by clicking on the table header.

The HI, OH, Recombination Line Survey of the Milky Way (THOR) Survey Dataverse (Harvard-Smithsonian Center for Astrophysics)

Harvard Dataverse > MilkyWay3D Dataverse > The HI, OH, Recombination Line Survey of the Milky Way (THOR) Survey Dataverse

The THOR survey is a galactic plane survey covering $15^\circ < l < 67^\circ$ and $b < |1^\circ|$. It consists of HI 21 cm observations, 20 recombination lines and 1-2 GHz continuum data at a 20" spatial resolution. One of its main science goals is understanding the dynamics of the interstellar medium and how clouds transition from the atomic to the molecular phase. The link to the homepage of the THOR survey can be found [here](#).

The "Paper" of the Future

Alyssa Goodman, Josh Peek, Alberto Accomazzi, Chris Beaumont, Christine L. Borgman, How-Huan Hope Chen, Merce Crossas, Christopher Erdmann, August Muench, Alberto Pape, Curtis Wong

1 Preamble

A variety of research on human cognition demonstrates that humans learn and communicate best when more than one processing system (e.g. visual, auditory, touch) is used. And, related research also shows that, no matter how technical the material, most humans also retain and process information best when they can put a narrative "story" to it. So, when considering the future of scholarly communication, we should be careful not to do bilheli away with the linear narrative format that articles and books have followed for centuries. Instead, we should enrich it.

Much more than text is used to communicate in Science. Figures, which include images, diagrams, graphs, charts, and more, have enriched scholarly articles since the time of Galileo, and ever-growing volumes of data underpin most scientific papers. When scientists communicate face-to-face, as in talks or small discussions, these figures are often the focus of the ability to manipulate the figures, and to explain and shows with demonstrations—how rich records of scientific discourse, figures, audio, video, and commenting.

After Galileo discovered the first four moons of Jupiter, it took nearly three hundred years to discover the next one.

TEN QUESTIONS TO ASK WHEN CREATING A VISUALIZATION

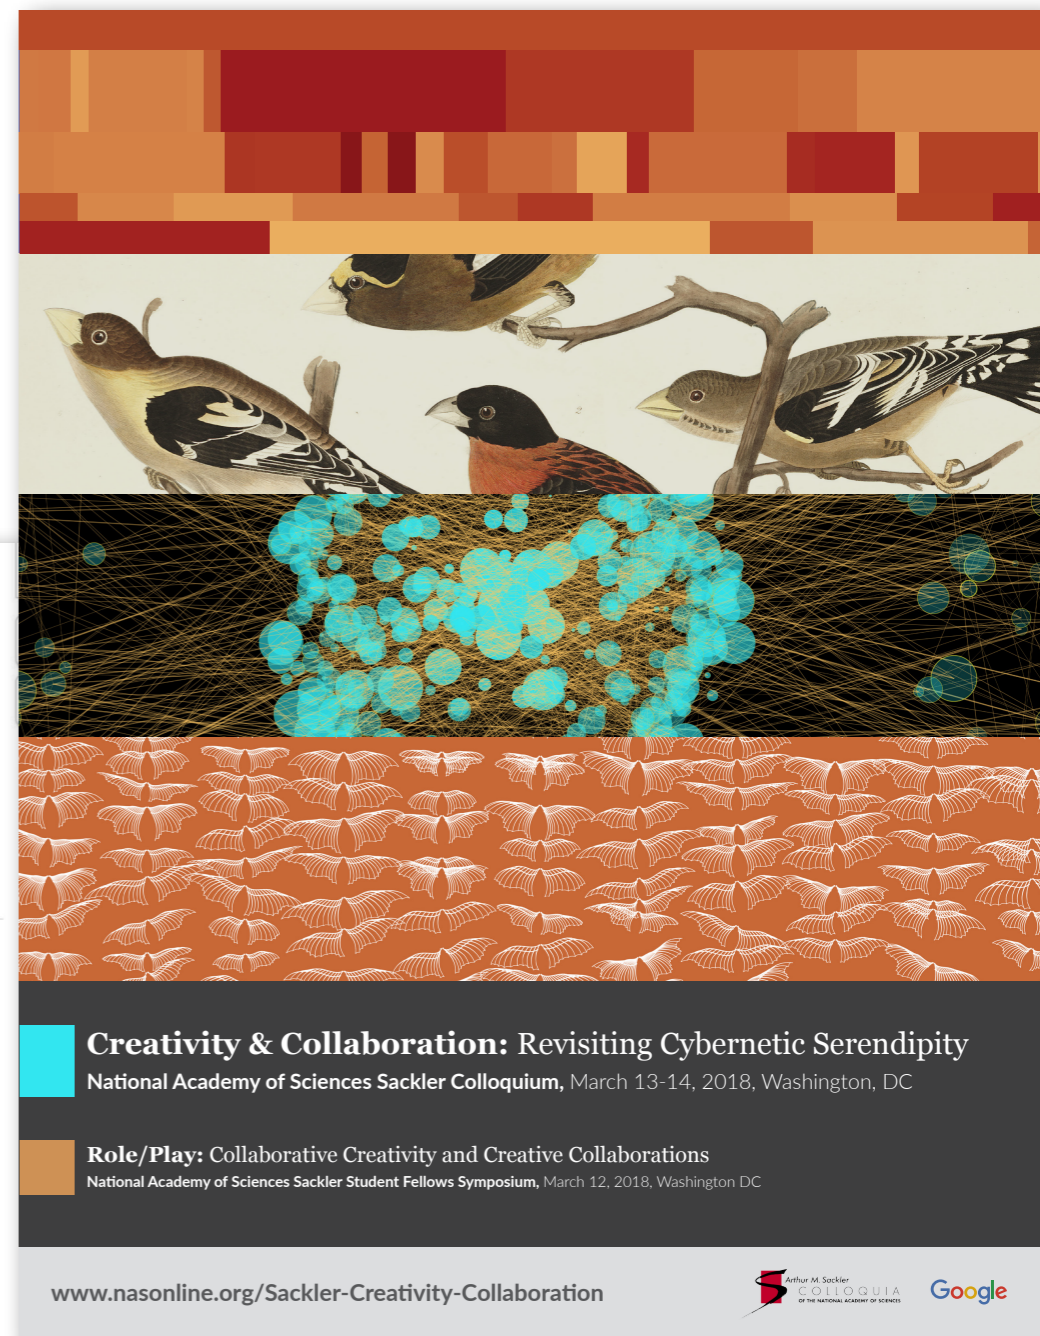

The 10 Questions

1. **Who** | *Who is your audience? How expert will they be about the subject and/or display conventions?*
2. **Explore-Explain** | *Is your goal to explore, document, or explain your data or ideas, or a combination of these?*
3. **Feature & Pattern Recognition** | *Is feature and/or pattern recognition, a goal?*
4. **Predictions & Uncertainty** | *Are you making a comparison between data and/or predictions? Is representing uncertainty a concern?*
5. **Dimensions** | *What is the intrinsic number of dimensions (not necessarily spatial) in your data, and how many do you want to show at once?*
6. **Categories & Clustering** | *Are there natural, or imposed, categories within the data? Are you interested in clustering?*
7. **Abstraction & Accuracy** | *Do you need to show all the data, or is summary or abstraction OK?*
8. **Context & Scale** | *Can you, and do you want to, put the data into a standard frame of reference, coordinate system, or show scale(s)?*
9. **Metadata** | *Do you need to display or link to non-quantitative metadata? (including captions, labels, etc.)*
10. **Display Modes** | *What display modes might be used in experiencing your display?*

2009

2015

glue
multidimensional data exploration

enabled by d3.js (javascript) outputs

d3po

d3po is a project designed to allow an astronomer (or anyone), with no special data visualization skills, to make an interactive, publication-quality figure that has staged builds and linked brushing through scatter plots. Our current version can be previewed at d3po.org, and represents a figure from upcoming work by graduate student Elisabeth Newton. The figure describes how metallicity affects color in cool stars, and represents a nice use case for d3po. Try clicking and dragging in the scatter plots to understand the power of linked brushing in published figures.

Right now we are in search of alpha testers, who have figures that could be made interactive and who are willing to get their hands a little dirty (No javascript skills needed). In future versions, we plan to link to [glue](#) to allow the creation of d3po figures interactively. We are also exploring [implementation](#) of d3po within presentations and within [authorea](#). Full 1.0 version expected in January 2014.

Installing your own d3po server

```
git clone git@github.com:adrm/d3po.git
cd d3po
virtualenv --no-site-packages venv
source venv/bin/activate
pip install -r pip-requirements.txt
python run.py
```

- The Strangers

After Galileo discovered the first four moons of Jupiter, it took nearly three hundred years to discover the next one.

[demo]

Many thanks to Alberto Pepe, Josh Peek, Chris Beaumont, Tom Robitaille, Adrian Price-Whelan, Elizabeth Newton, Michelle Borkin & Matteo Cantiello for making this possible.

Figure 2 | Comparison of the 'dendrogram' and 'CLUMPFIND' feature-identification algorithms as applied to ^{13}CO emission from the L1448 region of Perseus. **a**, 3D visualization of the surfaces indicated by colours in the dendrogram shown in **c**. Purple illustrates the smallest scale self-gravitating structures in the region corresponding to the leaves of the dendrogram; pink shows the smallest surfaces that contain distinct self-gravitating leaves within them; and green corresponds to the surface in the data cube containing all the significant emission. Dendrogram branches corresponding to self-gravitating objects have been highlighted in yellow over the range of T_{mb} (main-beam temperature) test-level values for which the virial parameter is less than 2. The x - y locations of the four 'self-gravitating' leaves labelled with billiard balls are the same as those shown in Fig. 1. The 3D visualizations show position-position-velocity (p - p - v) space. RA, right ascension; dec., declination. For comparison with the ability of dendrograms (**c**) to track hierarchical structure, **d** shows a pseudo-dendrogram of the CLUMPFIND segmentation (**b**), with the same four labels used in Fig. 1 and in **a**. As 'clumps' are not allowed to belong to larger structures, each pseudo-branch in **d** is simply a series of lines connecting the maximum emission value in each clump to the threshold value. A very large number of clumps appears in **b** because of the sensitivity of CLUMPFIND to noise and small-scale structure in the data. In the online PDF version, the 3D cubes (**a** and **b**) can be rotated to any orientation, and surfaces can be turned on and off (interaction requires Adobe Acrobat version 7.0.8 or higher). In the printed version, the front face of each 3D cube (the 'home' view in the interactive online version) corresponds exactly to the patch of sky shown in Fig. 1, and velocity with respect to the Local Standard of Rest increases from front (-0.5 km s^{-1}) to back (8 km s^{-1}).

data, CLUMPFIND typically finds features on a limited range of scales, above but close to the physical resolution of the data, and its results can be overly dependent on input parameters. By tuning CLUMPFIND's two free parameters, the same molecular-line data set⁸ can be used to show either that the frequency distribution of clump mass is the same as the initial mass function of stars or that it follows the much shallower mass function associated with large-scale molecular clouds (Supplementary Fig. 1).

Four years before the advent of CLUMPFIND, 'structure trees'⁹ were proposed as a way to characterize clouds' hierarchical structure

using 2D maps of column density. With the help of 2D work as inspiration, we have developed a structure-identification algorithm that abstracts the hierarchical structure of a data cube into an easily visualized representation called a dendrogram, well developed in other data-intensive applications of tree methodologies so far. Dendrograms are almost exclusively within the area of astronomy, where 'merger trees' are being used with increasing frequency.

Figure 3 and its legend explain the dendrogram process schematically. The dendrogram quantifies the hierarchical structure of a data cube, with each node explained in Supplementary Methods. The dendrogram is determined almost entirely by the input data, and is insensitive to algorithm parameters. It is a hierarchical tree structure possible on paper and 2D screen, but it is a 3D object (see Fig. 3 and its legend). The dendrogram is a cross, which eliminates dimensions, but it is a 3D object preserving all information. The dendrogram is a 3D object. Numbered 'billiard ball' labels are used to track features between a 2D map (see Fig. 1) and a sorted dendrogram (see Fig. 2).

A dendrogram of a spectral line data cube is a 3D object of key physical properties. The dendrogram is a 3D object, such as radius (R), velocity dispersion (σ_v), and luminosity (L). The volumes can have any shape, and are defined by the significance of the especially elongated features (see Fig. 2a). The luminosity is an approximate proxy for mass, such that $M_{\text{lum}} = X_{13\text{CO}} L_{13\text{CO}}$, where $X_{13\text{CO}} = 8.0 \times 10^{20} \text{ cm}^{-2} \text{ K}^{-1} \text{ s}$ (ref. 15; see Supplementary Methods and Supplementary Fig. 2). The derived values for size, mass and velocity dispersion can then be used to estimate the role of self-gravity at each point in the hierarchy, via calculation of an 'observed' virial parameter, $\alpha_{\text{obs}} = 5\sigma_v^2 R / GM_{\text{lum}}$. In principle, extended portions of the tree (Fig. 2, yellow highlighting) where $\alpha_{\text{obs}} < 2$ (where gravitational energy is comparable to or larger than kinetic energy) correspond to regions of p - p - v space where self-gravity is significant. As α_{obs} only represents the ratio of kinetic energy to gravitational energy at one point in time, and does not explicitly capture external over-pressure and/or magnetic fields¹⁶, its measured value should only be used as a guide to the longevity (boundedness) of any particular feature.

Figure 3 | Schematic illustration of the dendrogram process. Shown is the construction of a dendrogram from a hypothetical one-dimensional emission profile (black). The dendrogram (blue) can be constructed by 'dropping' a test constant emission level (purple) from above in tiny steps (exaggerated in size here, light lines) until all the local maxima and mergers are found, and connected as shown. The intersection of a test level with the emission is a set of points (for example the light purple dots) in one dimension, a planar curve in two dimensions, and an isosurface in three dimensions. The dendrogram of 3D data shown in Fig. 2c is the direct analogue of the tree shown here, only constructed from 'isosurface' rather than 'point' intersections. It has been sorted and flattened for representation on a flat page, as fully representing dendrograms for 3D data cubes would require four dimensions.

A role for self-gravity at multiple length scales in the process of star formation

Alyssa A. Goodman^{1,2}, Erik W. Rosolowsky^{2,3}, Michelle A. Borkin^{1,4}, Jonathan B. Foster², Michael Halle^{1,4}, Jens Kauffmann^{1,2} & Jaime E. Pineda²

Self-gravity plays a decisive role in the final stages of star formation, where dense cores (size ~ 0.1 parsecs) inside molecular clouds collapse to form star-plus-disk systems. But self-gravity's role at earlier times (and on larger length scales, such as ~ 1 parsecs) is unclear: some molecular cloud simulations that do not include self-gravity suggest that 'turbulent fragmentation' alone is sufficient to create a mass distribution of dense cores that resembles, and sets, the stellar initial mass function. Here we report a 'dendrogram' (hierarchical tree-diagram) analysis that reveals that self-gravity plays a significant role over the full range of possible scales traced by ^{13}CO observations in the L1448 molecular cloud, but not everywhere in the observed region. In particular, more than 90 per cent of the compact 'pre-stellar cores' traced by peaks of dust emission are projected on the sky within one of the dendrogram's self-gravitating 'leaves'. As these peaks mark the locations of key physical properties, such as radius (R), velocity dispersion (σ_v), and luminosity (L), the dendrogram's self-gravitating 'leaves' (Fig. 2a). The luminosity is an approximate proxy for mass, such that $M_{\text{lum}} = X_{13\text{CO}} L_{13\text{CO}}$, where $X_{13\text{CO}} = 8.0 \times 10^{20} \text{ cm}^{-2} \text{ K}^{-1} \text{ s}$ (ref. 15; see Supplementary Methods and Supplementary Fig. 2). The derived values for size, mass and velocity dispersion can then be used to estimate the role of self-gravity at each point in the hierarchy, via calculation of an 'observed' virial parameter, $\alpha_{\text{obs}} = 5\sigma_v^2 R / GM_{\text{lum}}$. In principle, extended portions of the tree (Fig. 2, yellow highlighting) where $\alpha_{\text{obs}} < 2$ (where gravitational energy is comparable to or larger than kinetic energy) correspond to regions of p - p - v space where self-gravity is significant. As α_{obs} only represents the ratio of kinetic energy to gravitational energy at one point in time, and does not explicitly capture external over-pressure and/or magnetic fields¹⁶, its measured value should only be used as a guide to the longevity (boundedness) of any particular feature.

A role for self-gravity at multiple length scales in the process of star formation

Alyssa A. Goodman^{1,2}, Erik W. Rosolowsky^{2,3}, Michelle A. Borkin^{1†}, Jonathan B. Foster², Michael Halle^{1,4}, Jens Kauffmann^{1,2} & Jaime E. Pineda²

Self-gravity plays a decisive role in the final stages of star formation, where dense cores (size ~0.1 parsecs) inside molecular clouds collapse to form star-plus-disk systems¹. But self-gravity's role at earlier times (and on larger length scales, such as ~1 parsec) is unclear; some molecular cloud simulations that do not include self-gravity suggest that 'turbulent fragmentation' alone is sufficient to create a mass distribution of dense cores that resembles, and sets, the stellar initial mass function². Here we report a 'dendrogram' (hierarchical tree-diagram) analysis that reveals that self-gravity plays a significant role over the full range of possible scales traced by ¹³CO observations in the L1448 molecular cloud, but not everywhere in the observed region. In particular, more than 90 per cent of the compact 'pre-stellar cores' traced by peaks of dust emission³ are projected on the sky within one of the dendrogram's self-gravitating 'leaves'. As these peaks mark the locations of already-forming stars, or of those probably about to form, a self-gravitating cocoon seems a critical condition for their exist-

overlapping features as an option, significant emission found between prominent clumps is typically either appended to the nearest clump or turned into a small, usually 'pathological', feature needed to encompass all the emission being modelled. When applied to molecular-line

ON A GREAT NEBULOUS REGION AND ON THE QUESTION OF ABSORBING MATTER IN SPACE AND THE TRANSPARENCY OF THE NEBULAE
By E. E. BARNARD

While photographing the region of the great nebula of ρ Ophiuchi (which I had found with the Willard lens) at the Lick Observatory in 1893, the plates with the small lantern lens (1 1/2 inches diameter, also attached to the Willard mounting) showed a remarkable nebula involving the 4.5 magnitude star ν Scorpii (Plate I). It had not been noticed on the Willard lens photograph, where it was very faint and near the edge of the plate. The discovery of this object therefore is due to the small lantern lens.

ABSTRACT

We present an overview of data available for the Ophiuchus and Perseus molecular clouds from Phase I of the COMPLETE Survey of Star-Forming Regions. This survey provides a range of data complementary to the *Spitzer* Legacy Program “From Molecular Cores to Planet Forming Disks.” Phase I includes the following: extinction maps derived from the Two Micron All Sky Survey (2MASS) near-infrared data using the NICER algorithm; extinction and temperature maps derived from *IRAS* 60 and 100 μm emission; H I maps of atomic gas; ^{12}CO and ^{13}CO maps of molecular gas; and submillimeter continuum images of emission from dust in dense cores. Not unexpectedly, the morphology of the regions appears quite different depending on the column density tracer that is used, with *IRAS* tracing mainly warmer dust and CO being biased by chemical, excitation, and optical depth effects. Histograms of column density distribution are presented, showing that extinction as derived from 2MASS NICER gives the closest match to a lognormal distribution, as is predicted by numerical simulations. All the data presented in this paper, and links to more detailed publications on their implications, are publicly available at the COMPLETE Web site.

Key words: ISM: clouds — stars: formation — surveys

Who, How, and Who's Paying?

The **ADS All Sky Survey** was first funded via a 2012 grant from the **NASA ADAP** program to Seamless Astronomy, in collaboration with CDS, Astrometry.net and Microsoft Research.

Articles-on-the-Sky

was first deployed in 2014, using APIs from WWT (Microsoft Research, now AAS) and CDS (Aladin)

Images-on-the-Sky

relies on the astrometry.net, Zooniverse, IOP/AAS Astronomy Image Explorer and WorldWide Telescope platforms, and it is funded by the **American Astronomical Society**, in addition to the NASA ADAP grant.

These projects rely on open source software, primarily hosted on **GitHub**.

WORDS FROM THE RESEARCHER

"Your contributions unlock the information from old astronomy journals. Thank you and enjoy the images!"

ABOUT ASTRONOMY REWIND

This project is part of an ongoing NASA-funded effort aimed at turning the SAO/NASA Astrophysics Data System (ADS) into a data resource. The result will be a database of astro-referenced images, i.e., images of the sky for which coordinates, orientation, and pixel scale will be publicly available through NASA data archives, the Astronomy Image Explorer, and World Wide Telescope, thanks to your help!
